1030.01 General

The primary function of delineation is to provide the visual information needed by a driver to operate a vehicle in a variety of situations. Delineation includes the marking of highways with painted or more durable pavement marking lines and symbols, guideposts, and other devices such as curbs (see [Chapter 1230](#)). These devices use retroreflectance, which is the reflecting of light from a vehicle's headlights back to the driver, to enhance an object's visibility at nighttime. It is important to maintain an adequate level of retroreflectivity for both traffic signs and traffic markings for motorists during hours of darkness and during adverse weather conditions.

Delineation is a required safety item of work and is addressed on all projects.

A decision to omit delineation work can only be justified if the existing delineation is unaffected by construction and an evaluation of crash rates clearly shows that delineation is not a contributing factor. The Washington State Department of Transportation (WSDOT) uses the latest edition of the MUTCD as a guide for the design, location, and application of delineation.

Consult with the region Traffic Office early in the design process to ensure the proposed delineation is compatible with WSDOT policy and region preference. These policies and preferences address both the type of markings and the material selection.

1030.03 Definitions

coefficient of retroreflection (R_L) A measure of retroreflection.

delineation Any method of defining the roadway operating area for the driver.

durability A measure of a traffic line's resistance to the wear and deterioration associated with abrasion and chipping.

extrude A procedure for applying marking material to a surface by forcing the material through a die to give it a certain shape.

glass beads Small glass spheres used in highway pavement markings to provide the necessary retroreflectivity.

mcd/m²/lux Pavement marking retroreflectivity is represented by the coefficient of retroreflected luminance (R_L) measured in millicandelas per square meter.

mil Unit of measurement equivalent to 0.001 inches.

MUTCD *Manual on Uniform Traffic Control Devices*.

pavement marking A colored marking applied to the pavement to provide drivers with guidance and other information.

retroreflection The phenomenon of light rays striking a surface and being returned directly back to the source of light.

retroreflectometer An instrument used to measure retroreflectivity.

spraying A procedure for applying marking material to a surface as a jet of fine liquid particles.

service life The service life of a pavement marking is the time or number of traffic passages required for its retroreflectivity to decrease from its initial value to a minimum threshold value indicating that the marking needs to be refurbished or replaced.

traffic paint A pavement marking material that consists mainly of a binder and a solvent. The material is kept in liquid form by the solvent, which evaporates upon application to the pavement, leaving the binder to form a hard film.

wet film thickness Thickness of a pavement marking at the time of application without glass beads.

1030.04 Pavement Markings

(1) Pavement Marking Types

Pavement markings have specific functions: they guide the movement of traffic and they promote safety on the highway. In some cases, they are used to supplement the messages of other traffic control devices. In other cases, markings are the only way to convey a message without distracting the driver. Pavement markings are installed and maintained to provide adequate performance year round. Adequate performance is defined as meaning the marking meets or exceeds the standards of both daytime and nighttime visibility.

Pavement markings are classified as either *longitudinal* or *transverse*. Centerlines, lane lines (where applicable), and edge lines (except as noted) are required on all paved state highways unless an exception is granted, with justification, by the State Traffic Engineer. Guidelines for the application of various pavement markings are provided in the *Standard Plans* and the MUTCD.

(a) Longitudinal Pavement Markings

Longitudinal pavement markings define the boundary between opposing traffic flows, and they identify the edges of traveled way, multiple traffic lanes, turn lanes, and special-use lanes. The *Standard Plans* shows the dimensions of longitudinal pavement markings. Longitudinal pavement markings are as follows:

barrier centerline A very wide—18 inches minimum, usually 20 inches: five 4-inch lines—solid yellow line or a combination of two single 4-inch solid yellow lines with yellow crosshatching between the lines, with a total width not less than 18 inches, used to separate opposing traffic movements where all movements over the line are prohibited. Barrier centerline locations require the approval of the region Traffic Engineer and Access Engineer.

centerline A broken yellow line used to separate lanes of traffic moving in opposite directions, where passing in the opposing lane is allowed.

dotted extension line A broken white or yellow line that is an extension of an edge line or centerline used at exit ramps, intersections on horizontal curves, multiple turn lanes, and other locations where the direction of travel for through traffic is unclear.

double centerline Two parallel solid yellow lines used to separate lanes of traffic moving in opposite directions where passing in the opposing lane is prohibited.

double lane line Two solid white lines used to separate lanes of traffic moving in the same direction where crossing the lane line marking is prohibited.

double wide lane line Two solid wide white lines used to separate a concurrent preferential lane of traffic where crossing is prohibited.

drop lane line A wide broken white line used in advance of a wide line to delineate a lane that ends at an off-ramp or intersection.

edge line A solid white or yellow line used to define the outer edges of the traveled way. Edge lines are not required where curbs or sidewalks are 4 feet or less from the traveled way.

lane line A broken white line used to separate lanes of traffic moving in the same direction.

no-pass line A solid yellow line used in conjunction with a centerline where passing in the opposing lane is prohibited.

reversible lane line Two broken yellow lines used to delineate a lane where traffic direction is periodically reversed.

solid lane line A solid white line used to separate lanes of traffic moving in the same direction where crossing the lane line marking is discouraged. Note: While this marking is in the MUTCD, it may not be in wide use by WSDOT as it is the same as the edge line.

two-way left-turn centerline Two yellow lines, one solid and one broken, used to delineate each side of a two-way left-turn lane.

wide broken lane line A wide broken white line used to designate a portion of a high-occupancy vehicle (HOV) lane located on a divided highway where general-purpose vehicles may enter to make an exit.

wide dotted lane line A wide broken white line used to designate a portion of a high-occupancy vehicle (HOV), or business access and transit (BAT) lane located on an arterial highway where general-purpose vehicles may enter to make a turn at an intersection.

wide lane line A wide solid white line used to separate lanes of traffic moving in the same direction, at ramp connections, storage lanes at intersections, and high-occupancy vehicle (HOV) lanes, or at business access and transit (BAT) lanes, bike lanes, and other preferential lanes where crossing is discouraged.

(b) **Transverse Pavement Markings**

Transverse pavement markings define pedestrian crossings and vehicle stopping points at intersections. They are also used to warn motorists of approaching conditions, required vehicular maneuvers, or lane usage. Typical transverse pavement markings are as follows:

access parking space symbol A white marking used to designate parking stalls provided for motorists with disabilities. The marking may have an optional blue background and white border.

aerial surveillance marker White markings used at one-mile and one-half-mile intervals on sections of highways where the State Patrol uses airplanes to enforce speed limits.

bicycle lane symbol A white marking consisting of a symbol of a bicyclist and an arrow used in a marked bike lane. (See the [Standard Plans](#) for an example of the bicycle lane symbol.) The bicycle lane symbol is to be placed immediately after an intersection and at other locations as needed (see the MUTCD). Typical spacing is 500 feet, with a maximum distance of 1,500 feet.

crosswalk line A series of parallel solid white lines used to define a pedestrian crossing.

drainage marking A white line used to denote the location of a catch basin, grate inlet, or other drainage feature in the shoulder of a roadway.

HOV symbol A white diamond marking used for high-occupancy vehicle lanes. The spacing of the markings is an engineering judgment based on the conditions of use. Typical spacing is 1000 feet for divided highways and 500 feet for arterial highways.

railroad crossing symbol A white marking used in advance of a railroad crossing where grade crossing signals or gates are located or where the posted speed of the highway is 40 mph or higher.

stop line A solid white line used to indicate the stopping point at an intersection or railroad crossing.

traffic arrow A white marking used in storage lanes and two-way left-turn lanes to denote the direction of turning movement. Arrows are also used at ramp terminals and intersections on divided highways to discourage wrong-way movements.

traffic letters White markings forming word messages, such as “ONLY,” used in conjunction with a traffic arrow at drop-lane situations. Traffic letters are not required for left- and right-turn storage lanes where the intended use of the lane is obvious.

wide line A wide solid line used for traffic islands, hash marks, chevrons, and other applications. A wide line used in conjunction with a centerline marking shall be yellow. A wide line used in conjunction with a lane line or right edge line marking shall be white.

(2) Pavement Marking Materials

Pavement markings are applied using various materials. These materials are divided into two categories: paint and plastic. When selecting the pavement marking material to use in a project, consider the initial cost of the material and its service life; the location; the traffic conditions; the snow and ice removal practices of the particular maintenance area; and the region’s ability to maintain the markings.

Both painted and plastic pavement markings can accomplish the goal of providing a visible (daytime) and retroreflective (nighttime) pavement marking at the completion of a contract. The difference between the two marking materials is the projected service life of the markings. Paint used on sections of highway subjected to high traffic volumes and/or snow-removal operations might have a service life of only two to three months. Maintenance crews cannot restripe a highway during winter months; therefore, if a painted marking wears out prematurely, the highway will not have a stripe until maintenance crews can restripe in April or May. When these conditions are encountered in a highway project, it is strongly recommended that the designer specify one of the more durable plastic marking materials and application types that will provide an adequate service life for the marking.

For the recommended pavement marking material for different highway types and snow-removal practices, see [Exhibit 1030-1](#). Consult with the region’s Traffic and Maintenance offices to select the best material for the project.

(a) Paint

Paint is the most common pavement marking material. It is relatively easy to apply and dries quickly (30–90 seconds in warm, dry weather) after application. This allows the application to be a moving operation, which minimizes traffic control costs and delays to the roadway users. On construction contracts, paint is applied with two coats: the first coat is 10 mils thick, followed by a second coat 15 mils thick. The disadvantage of using paint as a pavement marking material is its short service life when subjected to traffic abrasion, sanding, or snow-removal activities. Specify paint only where it will have a service life that will provide a retroreflective stripe until maintenance crews can repaint the line and extend its service life until the next repainting.

Paint is one of two material types dependent upon the solids carrier: solvent or waterborne. The designer is encouraged to specify waterborne paint, which has proven to be more durable than solvent paints. Solvent paint is also subject to a monetary penalty because it contains a high level of volatile organic compounds (VOCs). There is an Environmental Protection Agency (EPA) Clean Air Act penalty assessed on solvent paint that is passed on to those who purchase solvent paint in quantity.

Durable waterborne paint or high-build waterborne paint is a paint technology developed in 1999. This paint is formulated to allow application thicknesses of 20 to 30 mils. It is more durable than standard waterborne paint and, applied at these thicknesses, provides additional service life. The additional thickness permits the use of larger glass beads that enhance wet night retroreflectivity. This paint has been tested on two WSDOT contracts and is available for the WSDOT Striping Maintenance Crews. It will be available for use on contracts in the near future.

Low-temperature waterborne paint is another recent development (2006) in paint technology. This paint is intended to extend the paint season later into the fall, although it may also be used earlier in the spring. The paint is formulated for application temperatures of 35° Fahrenheit and rising. This paint is available for WSDOT Striping Maintenance Crews. It will be available for use on contracts in the near future.

(b) Plastic

Plastic markings have a higher installation cost than paint. They can, however, be a more cost-effective measure than paint because of their longer service life. Plastic marking materials may provide a year-round retroreflective pavement marking, while paint may not last until the next restriping. Plastic marking materials currently listed in the *Standard Specifications* include the following:

1. Type A: Liquid Hot Applied Thermoplastic

Thermoplastic material consists of resins and filler materials in solid form at room temperature. The material is heated to a semiliquid, molten state (400° Fahrenheit) and is then applied to the roadway by spray or extrusion methods. This material can be used for both transverse and longitudinal line applications. Special equipment is required for both the initial application and subsequent maintenance renewal. Sprayed material can be applied at

a thickness of 30 mils and dries in 30 to 60 seconds. The service life of material applied in this manner is slightly longer than that of paint. Extruded material is applied at a thickness of 125 mils and has a drying time of 15 minutes. This material can be applied as a flat line or applied with ridges or profiles (bumps) that enhance wet night visibility. These profiles produce a rumble effect similar to raised pavement markers when a vehicle crosses over the marking. (Profiles come in the shape of a raised bar at set intervals along and formed simultaneously with the extruded baseline.)

2. **Type B: Preformed Fused Thermoplastic**

This material consists of a mixture of pigment, fillers, resins, and glass beads that is factory produced in sheet form 125 mils thick. The material is applied by heating (drying) the pavement and top heating the material. The heating process fuses the preformed thermoplastic material to the pavement surface. These materials, which are used for transverse markings, are available in white, red, blue, and other colors.

3. **Type C: Cold Applied Preformed Tape**

Preformed tape is composed of thermoplastic or other materials that are fabricated under factory conditions. After curing, the material is cut to size and shipped to the work site in rolls or in flat pieces. The material is then applied to the roadway with an adhesive on the underside of the tape. Preformed tape is available in a thickness of 60 mils, 90 mils, or 125 mils. (WSDOT does not currently specify 125 mil tape.) The most durable application of preformed tape is achieved when the tape is either inlaid (rolled) into hot asphalt and the top of the tape is flush with the surface of the pavement, or it is placed in a groove cut into the pavement surface and the top of the tape is slightly below the surface of the pavement.

ASTM has classified preformed tape into two categories: Type 1 and Type 2. Type 1 tape has a profiled surface and a requirement to have a retroreflectivity of over 500 mcd/m²/lux. Type 1 tape has proven to be very durable. It is used on high-volume, high-speed highways. Type 2 tape has a flat surface and a requirement to have a retroreflectivity of over 250 mcd/m²/lux. Field tests show that Type 2 tape has a shorter service life than Type 1 tape.

4. **Type D: Liquid Cold Applied Methyl Methacrylate (MMA)**

Methyl methacrylate can be applied by either spraying or extrusion. Sprayed applications can be one or two coats, 30 to 45 mils thick. Extruded applications are 90 mils thick for dense asphalt or PCC pavement, or 120 mils thick for open-graded asphalt pavement. MMA can also be extruded using specialized equipment to produce a textured line 150 mils thick. The material is not heated and can be applied within an approximate temperature range of 40° to 105° Fahrenheit, provided the pavement surface is dry. The material can be used for both transverse and longitudinal applications. The material can also be applied with profiles (bumps) that slightly enhance wet night retroreflectivity. The profiles also produce a rumble effect similar to raised pavement markers.

5. Type E: Plural Component Pavement Marking Materials

Type E marking materials are two-part materials that can be Type E1: Hybrid/Modified Epoxy (Modified Urethane), Type E2: Polyurea, or Type E3: Liquid Cold Applied Methyl Methacrylate, which require a mix of materials to achieve a chemical reaction for formulation and bond. Type E marking materials are applied by spray with a top dressing of glass beads.

Type E marking materials should provide a service life of four to six years. If installed on mountain passes and heavy traffic areas, the service life may be reduced to one to three years. White shall have a minimum R_L of 330 $\text{mcd m}^{-2} \text{lx}^{-1}$ and yellow shall have a minimum R_L of 200 $\text{mcd m}^{-2} \text{lx}^{-1}$.

Type E marking materials may be used on all roadway classes. They may be renewed following a surface preparation to remove 90% of the existing marking material. The setting time for Type E material is usually very short and can reduce the traffic control concerns.

Type E marking materials have been successfully tested by WSDOT and are used by many other states. They are not currently in the *Standard Specifications* and must be included in contracts as a special provision at this time; they are intended to be a general special provision (GSP) in the near future. The specification includes compliance adjustment factors for material thickness and retroreflectivity.

(c) Glass Beads

Glass beads are small glass spheres used in highway markings to provide the necessary retroreflectivity. The beads are dropped onto the wet marking material immediately after it is applied (drop-on beads), or premixed into the wet marking material and dropped onto the wet marking material immediately after it is applied.

Proper installation of glass beads is critical to achieving good pavement marking retroreflectivity. Each glass bead works like a light-focusing lens, reflecting light back to the driver. Glass beads are embedded into the pavement marking material; for optimum performance, the bead is embedded between 55% and 60% of its diameter.

Large glass beads are effective when roads are wet. Large glass beads are not appropriate for paint as the paint is too thin to properly embed the large glass beads; therefore, WSDOT specifies small glass beads for paint applications.

The use of large glass beads is limited to high-build waterborne paint and other materials with a thickness of at least 22 mils.

(3) Pavement Marking Application Types

There are five application types used for pavement markings. Most pavement marking applications are applied directly to the pavement surface. In steel bit snow plowing areas, the pavement markings may be inlaid or grooved to protect the markings.

Because they are higher than the surrounding pavement surface, pavement markings are subject to rapid wear caused by traffic and snowplows. As they wear, they lose visibility and retroreflectivity, particularly in wet weather. Wear on the stripes can be greatly reduced and their service life considerably increased by placing them in a shallow groove in the surface of the pavement.

(a) Application Types

The five application types for pavement markings are:

1. Flat Lines

Flat lines are pavement marking lines with a flat surface.

2. Profiled Marking

A profiled pavement marking consists of a baseline thickness and a profiled thickness, which is a portion of the pavement marking line that is applied at a greater thickness than the baseline thickness. Profiles are applied using the extruded method in the same application as the baseline. The profiles may be slightly rounded if the minimum profile thickness is provided for the entire length of the profile. (See the *Standard Plans* for the construction details.)

3. Embossed Plastic Line

Embossed plastic lines consist of a flat line with transverse grooves. An embossed plastic line may also have profiles. (See the *Standard Plans* for the construction details.)

4. Inlaid Plastic Line

Inlaid plastic line is constructed by rolling Type C tape into hot mix asphalt (HMA) with the finish roller. This application is used infrequently by WSDOT and is not in the *Standard Specifications*.

5. Grooved Plastic Line

Grooved plastic line is constructed by cutting a groove into the pavement surface and spraying, extruding, or gluing pavement marking material into the groove. The groove depth is dependent upon the material used, the pavement surface, and the location. The groove is typically in the range of 20 to 250 mils deep and 4 inches wide. Coordinate with the region Traffic Office on the use and dimensions of grooved plastic line marking.

(4) Raised Pavement Markers

Raised pavement markers (RPMs) are installed as positioning guides with long line pavement markings. They can also be installed as a complete substitution for certain long line markings. RPMs have a service life of two years, and they provide good wet night visibility and a rumble effect. RPMs are made from plastic materials and are available in three different types:

- **Type 1** markers are 4 inches in diameter, $\frac{3}{4}$ inch high, and nonreflectorized.
- **Type 2** markers are 4 inches wide, $2\frac{1}{2}$ to 4 inches long, $\frac{3}{4}$ inch high, and reflectorized.
- **Type 3** markers are 6, 8, 10, or 12 inches wide, 4 inches long, $\frac{3}{4}$ inch high, and nonreflectorized.

Type 2 RPMs are not used as a substitute for right edge lines. They can only be used to supplement the right edge line markings at lane reductions, at sections with reduced lane widths such as narrow structures, and at the gore of exit ramps. All other applications supplementing right edge line markings require the approval of

the region Traffic Engineer. Type 3 RPMs are used in locations where additional emphasis is desired, including vehicle separations and islands. Approval by the region Traffic Engineer is required for all installations of Type 3 RPMs.

Reflectorized RPMs are not required for centerline and lane line applications in continuously illuminated sections of highway. However, if reflectorized RPMs are used at an intersection within an illuminated section, they are also provided throughout that section.

For raised pavement marker application details, see the *Standard Plans*.

(5) Recessed Raised Pavement Markers

Recessed raised pavement markers (RRPMs) are raised pavement markers (RPMs) installed in a groove ground into the pavement in accordance with the *Standard Plans*. RRPMs provide guidance similar to RPMs in ice chisel and steel blade snow-removal areas. RRPMs can also be used in rubber blade snow-removal areas in accordance with region policy.

Designer should be aware that the performance of RRPMs can be compromised, especially on curves, because the groove can block motorists' view of the markers. Also, the groove for RRPMs installed on flat grades can fill with water during rainstorms and cause the RRPM to be nonreflective.

RRPMs, when specified, are installed at the locations shown in the *Standard Plans* for Type 2W RPMs on multilane one-way roadways and Type 2YY RPMs on two-lane two-way roadways.

Do not recess side-to-side RPMs on wide dotted lane lines.

For recessed pavement marker application details, see the *Standard Plans*.

1030.05 Guideposts

(1) General

Guideposts are retroreflective devices mounted to a support post installed at the side of the roadway to indicate alignment. They are considered to be guidance devices rather than warning devices. Guideposts are used as an aid to nighttime driving primarily on horizontal curves; multilane divided highways; ramps; tangent sections where they can be justified due to snow, fog, or other reduced-visibility conditions; and at intersections without illumination.

(a) Types of Guideposts

The retroreflective device may be mounted on either a white or brown post. The types of guideposts and their application are as follows:

1. Type W

Type W guideposts have silver-white reflective sheeting, are facing traffic, and are used on the right side of divided highways, ramps, right-hand acceleration and deceleration lanes, intersections, and ramp terminals.

2. Type WW

Type WW guideposts have silver-white reflective sheeting on both sides and are used on the outside of horizontal curves on two-way undivided highways.

3. Type Y

Type Y guideposts have yellow reflective sheeting, are facing traffic, and are used on the left side of ramps, left-hand acceleration and deceleration lanes, ramp terminals, intersections on divided highways, median crossovers, and horizontal curves on divided highways.

4. Type YY

Type YY guideposts have yellow reflective sheeting on both sides and are used in the median on divided highways.

5. Type G1

Type G1 guideposts have silver-white reflective sheeting on both sides and green reflective sheeting below the silver-white sheeting on the side facing traffic. They are used at intersections of undivided highways without illumination.

6. Type G2

Type G2 guideposts have silver-white reflective sheeting on both sides and green reflective sheeting below the silver-white reflective sheeting on the back side. They are used at intersections of undivided highways without illumination.

(2) Placement and Spacing

Guideposts are placed not less than 2 feet and not more than 8 feet outside the outer edge of the shoulder. Place guideposts at a constant distance from the edge of the roadway. When an obstruction intrudes into this space, position the guideposts to smoothly transition to the inside of the obstruction. Guideposts are not required along continuously illuminated divided or undivided highways. (See [Exhibit 1030-2](#) for guidepost placement requirements and the *Standard Plans* for information on the different types and placement of guideposts.)

1030.06 Barrier Delineation

Traffic barriers are delineated where guideposts are required, such as bridge approaches, ramps, and other locations on unilluminated roadways (see [Exhibit 1030-2](#)). At these locations, the barrier delineation has the same spacing as that of guideposts. Barrier delineation is also required when the traffic barrier is 4 feet or less from the traveled way. Use a delineator spacing of no more than 40 feet at these locations.

Beam guardrail is delineated by either mounting flexible guideposts behind the rail or by attaching shorter flexible guideposts to the wood guardrail posts.

Concrete barrier is delineated by placing retroreflective devices on the face of the barrier about 6 inches down from the top. Consider mounting these devices on the top of the barrier at locations where mud or snow accumulates against the face of the barrier.

1030.07 Object Markers

Object markers are used to mark obstructions within or adjacent to the roadway. The MUTCD details three types of object markers. The Type 3 object marker with yellow and black sloping stripes is the most commonly used object marker.

The MUTCD contains criteria for the use of object markers to mark objects in the roadway and adjacent to the roadway. These criteria are to be followed in project design.

The terminal ends of impact attenuators are delineated with modified Type 3 object markers. These are the impact attenuator markers in the *Sign Fabrication Manual*. When the impact attenuator is used in a roadside condition, the marker with diagonal stripes pointing downward toward the roadway is used. When the attenuator is used in a gore where traffic will pass on either side, the marker with chevron stripes is used.

End of Roadway markers are similar to Type 1 object markers and are detailed in the MUTCD. They are used to alert users about the end of the roadway. The MUTCD criteria are to be followed in project design.

1030.08 Wildlife Warning Reflectors

Studies show that wildlife warning reflectors are ineffective at reducing the accident potential for motor vehicle/wildlife crashes. WSDOT policy is to no longer design, place, or maintain wildlife warning reflectors.

1030.09 Documentation

Refer to [Chapter 300](#) for design documentation requirements.

Notes:

- [1] Grooved Plastic is a line constructed by cutting a groove into the pavement surface and spraying, extruding, or gluing pavement marking material into the groove.
- [2] Plastic refers to methyl methacrylate (MMA), thermoplastic, or preformed tape.
- [3] For RPM substitute applications and RPM applications supplementing paint or plastic, see the [Standard Plans](#), Section M.
- [4] RRPMS refer to RPMs installed in a groove ground into the pavement. RRPMS are identified as "Recessed Pavement Markers" in the [Standard Specifications](#) and the [Standard Plans](#).
- [5] Type 2 RPMs are not required with painted or plastic centerline or lane line in illuminated sections.
- [6] PMMA refers to profiled methyl methacrylate.
- [7] Consult region striping policy.
- [8] FMMA refers to flat methyl methacrylate.
